

Decoding the neural correlates of dream recall from EEG using machine learning and Riemannian geometry

Arthur Dehgan, Tarek Lajnef, Raphael Vallat, Jean-Baptiste Eichenlaub, Perrine Marie Ruby, Irina Rish, and Karim Jerbi

+ Alexandre Louis

Riemannian decoding: replication of Fig. 2

Arthur's pipeline

Replication

My null distribution is computed by drawing a new epoch subsample at each permutation, whereas Arthur permutes the labels on a single fixed subsample. My null therefore also incorporates the subsampling variance, which widens it and scatters the thresholds instead of aligning them.

PSD topomaps, replicating Fig. 3

Arthur's pipeline

Replication

LDA decoding topomaps, replicating Fig. 4

Same background (per-electrode decoding accuracy); the significance criterion differs: Arthur flags an electrode via an analytical binomial threshold; I use a permutation test.

Note: i could not fully reproduce his exact star map because the threshold depends on N (epoch count from his info_data.csv), a file i don't have.

Fig. 5, partial replication

- *REGIONS (electrode-to-ROI mapping) imported from params.py, added to .gitignore, never committed. Our ROIs are not the same as theirs.*
- *The public code divides each band into 5 parts. The thesis version (combinations, gray) comes from unpublished code: our figure is a reconstruction.*
- *His dotted line is not a permutational threshold but an analytical binomial threshold, $\text{binom.isf}(0.001, N, 0.5)/N$, where N = the pool of epochs per stage (5,887 to 21,588), corresponding to 51–52%. This calculation treats each epoch as an independent trial, even though they are nested within 36 subjects. As a rough guide, an N at the subject level would place the threshold around 75%.*
- *Two combinations not included in his legend stand out in our analysis, including $\beta+\delta+\sigma$ in the prefrontal S2 at 66.78%, our best accuracy, which had not been observed until now.*

New features

FOOOF :

- Oscillatory power ratio on each band
- Aperiodic spectral exponent

New features

Complexity :

- Permutation entropy (default value = order 3)
- Higuchi fractal dimension (default $k_{\max} = 10$)
- Spectral entropy

Permutation entropy, order=3 (Cz)

Higuchi fractal dimension (Cz)

Spectral entropy (Cz)

Adding overlap

- **Role of overlap:** stabilize the estimators (better-conditioned SPD matrices, less noisy bootstrap), not gain fictitious statistical power
- **Overlap stays confined within a subject:** since a CV fold leaves out whole subjects (LPGO), a subject's overlapping epochs are always in the same fold together, never split between the training subjects and the held-out test subjects.
- **No data leakage:** the train/test split is done **per subject** (Leave-P-Subjects-Out), not per epoch, so all of a subject's epochs, including overlapping ones, fall on the same side of the split.

WINDOW	=	1000
OVERLAP	=	500
OVERLAP_COSP	=	0.75

Adding overlap

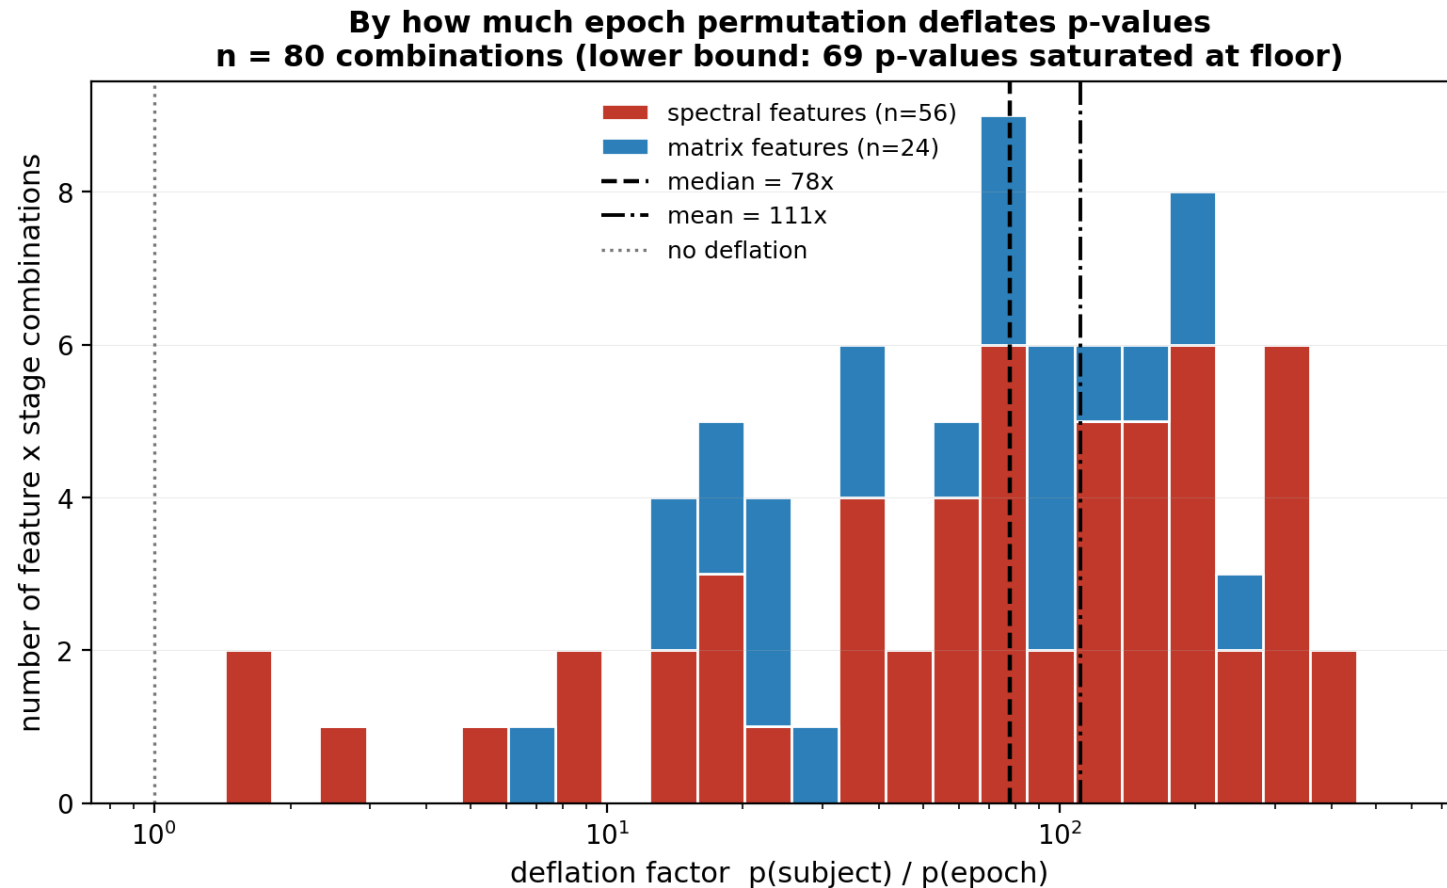

Overlap yields a mean gain of +0.62 pts, median +0.46, with 17/24 combos improving. The gain concentrates on `cosp_delta` (+2.0 to +2.2 pts across all stages), and to a lesser extent the S2 cospectra.

A new way to compute the permutations

■ High Recaller ■ Low Recaller

A new way to compute the permutations

Results after new perms

Stability of the Bootstrap Estimate

- **Convergence:** The average accuracy stabilizes well before 1,000 runs; the number of bootstrap samples does not affect the results.
- **Dispersion:** The variability across feature/stage combinations justifies the error bars and confirms that the significant effects are not due to a favorable draw.

Maxstats: across the 19 électrodes : PSD

And our new features

Maxstats: across all feature × stage combinations

Riemannian classifications, permutation sujet (RFX), non corrige (p brute, feature seule), $p < 0.05$

Riemannian classifications, permutation sujet (RFX), max-stat pooled sur la famille matricielle, $p < 0.05$

Distributions nulles par permutation sujet (RFX) | - - - : seuil max-stat pooled $p < 0.05$

sigma cospec, S2

alpha cospec, S2

delta cospec, SWS

delta cospec, NREM

Osc power ratio (fooof) & PSD

Features vectorielles modernisees (subject/RFX), max-stat pooled, psd_osc sur 5 bandes, $p < 0.05$

PSD bruts facon Arthur (subject/RFX), max-stat pooled, psd sur 5 bandes, $p < 0.05$

Effect of multiple testing correction, PSD sigma / S2 (subject perm, $p < 0.05$)

P-value survival curve by correction

P-value survival curve by correction family, subject scheme (RFX)

T-test : Permutation Level: What Changes and What Doesn't

The inconsistency in Fig. 3 :

“t-values” panel: RFX, permutation at the subject level

“accuracies” panel: FFX, permutation at the epoch level

=> contrast that stems in part from the criterion

Fig. 3, S2: EPOCH level permutation (FFX, $p < 0.001$) vs SUBJECT level (RFX, $p < 0.05$) decoding: IDENTICAL accuracy (only the null distribution changes); t-values: recomputed by level. Maxstat electrodes. Stars drop in RFX.

Approaches Explored and Discarded

Preprocessing:

- **ICA** (EOG rejection, threshold 0.6): accuracy drops to 44–54% compared to 54–69% in noica. ICA destroys discriminant signal. However, the threshold was set empirically using three converging methods.
- **ICLabel** (probability > 0.9), only 8% agreement with the EOG method; trained on wakefulness data and therefore unsuitable for sleep. Causes a drop in cosp_sigma/S2, our main result. Kept for comparison, not as part of the pipeline.
- **find_bads_muscle**, removed; no stable threshold range (CV 0.77–1.13 across the entire range); rejections confirmed as aberrant upon visual inspection. Z-score criterion for ICA, eliminated; 78.9% of subjects had zero rejections at $z = 2.5$; insufficient resolution with ~14 components per subject.
- **CAR** (Common Average Reference), removed; not recommended with fewer than ~64 electrodes; contaminates connectivity measurements and results in rank-deficient matrices.
- **AutoReject**, replaced by Potato.
- **And some others**

Approaches Explored and Discarded

Methods and Parameters :

- **FOOOF knee mode**, $\Delta R^2 = -0.0004$ across 139,000 spectra, 50× below the 0.02 threshold. Fixed value selected.
- **Linear subtraction for the oscillatory component**; values at $\sim 1e-10$, below the machine's epsilon, unusable. Ratio retained.
- **250 Hz**, under-resolution of the sigma band; abandoned in favor of 1,000 Hz.
- **EFS multi-feature**; extension beyond Arthur abandoned. Result: no super-combinations; redundant features; cosp_sigma dominates S2 and cosp_delta dominates SWS. Two issues specific to our version: the $\sim 84\%$ cross-state figure is an SPD aggregation artifact and not a reportable accuracy, and the p-value suffers from double-dipping (pool already preselected by maxstat, reselected at each permutation).
- **And some others**

TY everyone !!!
